Emergency supply of medicines

5

Emergency supply of medicines

For details of emergency supply at the request of a doctor, see *Medicines*, *Ethics and Practice*, No. 22, London, Pharmaceutical Press, 1999 (and subsequent editions).

The Medicines (Products Other Than Veterinary Drugs) (Prescription Only) Order 1983, as amended, allows exemptions from the Prescription Only requirements for emergency supply to be made by a person lawfully conducting a retail pharmacy business provided.

(a) that the pharmacist has interviewed the person requesting the prescription-only medicine and is satisfied:

 (i) that there is immediate need for the prescription only medicine and that it is impracticable in the circumstances to obtain a prescription without undue delay;

(ii) that treatment with the prescription-only medicine has on a previous occasion been prescribed by a doctor¹ for the person requesting it:

(iii) as to the dose which it would be appropriate for the person to take;

(b) that no greater quantity shall be supplied than will provide five days' treatment except when the prescription-only medicine is:

(i) an outtment, cream, or preparation for the relief of asthma in an acrosol dispenser when the smallest pack can be supplied,

(ii) an oral contraceptive when a full cycle may be supplied:

(iii) an antibiotic in liquid form for oral administration, when the smallest quantity that will provide a full course of treatment can be supplied; (c) that an entry shall be made in the prescription book stating;

(i) the date of supply;

(ii) the name, quantity and, where appropriate, the pharmaceutical form and strength;

(iii) the name and address of the patient;(iv) the nature of the emergency;

(d) that the container or package must be labelled to show:

(i) the date of supply;

(ii) the name, quantity and, where appropriate, the pharmaceutical form and strength:

(tii) the name of the patient;

(iv) the name and address of the pharmacy.

(v) the words 'Emergency supply

(e) that the prescription only medicine is not a substance specifically excluded from the emergency supply provision, and does not contain a Controlled Drug specified in schedules 1, 2, or 3 to the Misuse of Drugs Regulations 1985 except for phenobarbital or phenobarbital sodium for the freatment of epilepsy; for details see Medicines, Ethics and Practice, No. 22, London, Pharmaceutical Press, 1999 (and subsequent editions as available).

Royal Pharmaceutical Society's Guidelines

(1) The pharmacist should consider the medical consequences of *not* supplying.

(2) If the patient is not known to the pharmacist, the patient's identity should be established by way of appropriate documentation.

(3) It may occasionally be desirable to contact the prescriber, e.g. when the medicine requested has a potential for missive or the prescriber is not known to the obsamacist.

(4) Care should be taken to ask whether the patient's doctor has stopped the treatment, or whether the patient is taking any other medication (5) Except for conditions which occur infrequently (e.g. hay lever, asthma attack or migraine), a supply should not be made if the item requested was last prescribed more than 6 months ago.

(6) Consideration should be given to supplying less than 5 days' quantity if this is justified.

(7) Where a prescription is to be provided later, a record of emergency supply as required by law must still be made. It is good practice to add to the record the date that the prescription is received on. Payment for the medicine supplied is not a legal requirement, but may help to minimise the abuse of the emergency supply exemption. If an NHS prescription is to be provided, a refundable charge may be made.

Controlled drugs and drug dependence

PRESCRIPTIONS. Preparations which are subject to the prescription requirements of the Misuse of Drugs Regulations 1985, i.e. preparations specified in schedules 2 and 3, are distinguished throughout the BNF by the symbol [CD] (Controlled Drugs). The principal legal requirements relating to medical prescriptions are listed below.

Prescriptions ordering Controlled Drugs subject to prescription requirements must be signed and dated¹ by the prescriber and specify the prescriber's address. The prescription must always state in the prescriber's own handwriting2 in ink or otherwise so as to be indelible:

1. The name and address of the patient;

2. In the case of a preparation, the form³ and where appropriate the strength⁴ of the preparation;

The total quantity of the preparation, or the number of dose units, in both words and figures;5

4. The dose 6

A prescription may order a Controlled Drug to be dispensed by instalments; the amount of the instalments and the intervals to be observed must be specified.7 Prescriptions ordering 'repeats' on the same form are not permitted.

It is an offence for a doctor to issue an incomplete prescription and a pharmacist is not allowed to dispense a Controlled Drug unless all the information required by law is given on the prescription. Failure to comply with the regulations concerning the writing of prescriptions will result in inconvenience to patients and delay in supplying the necessary medicine.

A prescription is valid for 13 weeks from the date stated thereon.

- 2. Does not apply to prescriptions for temazepam. Oth erwise applies unless the prescriber has been specifi-cally exempted from this requirement or unless the prescription contains no controlled drug other than phenobarbital or phenobarbital sodium or a preparation containing either of these; the exemption does not apply to the date—a computer-generated date need not be deleted but the date must also be added by the prescriber.
- The dosage form (e.g. tablets) must be included on a Controlled Drugs prescription irrespective of whether it is implicit in the proprietary name (e.g. MST Continus) or of whether only one form is available. able.
- When more than one strength of a preparation exists the strength required must be specified.
- 5. Does not apply to prescriptions for temazepain.6. The instruction 'one as directed' constitutes a dose but 'as directed' does not
- A special form, FP10(HP)(ad), in Scotland HBP(A), is available to doctors in NHS drug treatment centres for prescribing cocaine, dextromoramide, diamor-phine, dipipanone, methadone, morphine, or pethidine by instalments for addicts (see also Terms of Service, paragraph 43). In Scotland general practi-tioners can prescribe by instalments on form GP10. In England and Wales forms FP10 and FP10(HP) are not suitable for this purpose but form FP10(MDA) is available. Important: in all cases a special licence is necessary to prescribe cocaine, diamorphine, or dipipanone for addicts except for treatment of mic disease or injury, for details see p. 8.

DEPENDENCE AND MISUSE. The most serious drugs of addiction are cocaine, diamorphine (heroin), morphine, and the synthetic opioids. For arrangements for prescribing of diamorphine, dipipanone or cocaine for addicts, see p. 8.

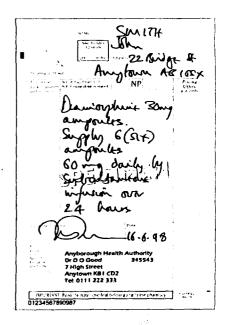

Despite marked reduction in the prescribing of amphetamines there is concern that abuse of illicit amfetamine and related compounds is widespread.

Owing to problems of abuse, flunitrazepam and temazepam are subject to additional controlled drug requirements (but temazepam remains exempt

from the additional prescribing requirements).

The principal barbiturates are now Controlled Drugs, but phenobarbital and phenobarbital sodium or a preparation containing either of these are exempt from the handwriting requirement but must fulfil all other controlled drug prescription requirements (important: the own handwriting exemption does not apply to the date; a computer-generated date need not be deleted but the date must also be added by the prescriber). Moreover, for the treatment of epilepsy phenobarbital and phenobarbital sodium are available under the emergency supply regulations (p. 5).

Cannabis (Indian hemp) has no approved medicinal use and cannot be prescribed by doctors. Its use is illegal but has become widespread. Cannabis is a mild hallucinogen seldom accompanied by a desire to increase the dose; withdrawal symptoms are unusual. Lysergide (lysergic acid diethylamide, LSD) is a much more potent hallucinogen; its use can lead to severe psychotic states in which life may be at

PRESCRIBING DRUGS LIKELY TO CAUSE DEPENDENCE OR MISUSE. The prescriber has three main responsibilities:

- 1. To avoid creating dependence by introducing drugs to patients without sufficient teason. In this context, the proper use of the morphine-like drugs is well understood. The dangers of other controlled drugs are less clear because recognition of dependence is not easy and its effects, and those of withdrawal, are less obvious. Perhaps the most notable result of uninhibited prescribing is that a very large number of patients in the country take tables which do them neither much good nor much harm, but are committed to them indefinitely because they cannot readily be stopped.
- 2. To see that the patient does not gradually increase the dose of a drug, given for good medical reasons, to the point where dependence becomes more likely. This tendency is seen especially with hypnotics and anxiolytics (for CSM advice see section 4.1). The prescriber should keep a close eye on the amount prescribed to prevent patients from accumulating stocks that would enable them to arrange their owardsage or even that of their families and friends. A minimal amount should be prescribed in the first instance, or when seeing a new patient for the first time.
- To avoid being used as an unwitting source of supply for addicts. Methods include visiting more than one doctor, fabricating stories, and forging prescriptions.

Patients under temporary care should be given only small supplies of drugs unless they present an unequivocal letter from their own doctors. Doctors should also remember that their own patients may be doing a collecting round with other doctors, especially in hospitals. It is sensible to decrease dosages steadily or to issue weekly or even daily prescriptions for small amounts if it is apparent that dependence is occurring.

The stealing and misuse of prescription forms could be minimised by the following precautions:

- (a) do not leave unattended if called away from the consulling room or at reception desks; do not leave in a car where they may be visible; when not in use, keep in a locked drawer within the surgery and at home;
- (b) draw a diagonal line across the blank part of the form under the prescription;
- (c) write the quantity in words and figures when prescribing drugs prone to abuse; this is obligatory for controlled drugs (see Prescriptions, above);
- (d) alterations are best avoided but if any are made they should be clear and unambiguous; add initials against altered items;
- (e) if prescriptions are left for collection they should be left in a safe place in a sealed envelope.

FRAVELLING ABROAD. Prescribed drugs listed in schedules 4 and 5 to the Misuse of Drugs Regulations 1985 are not subject to import or export licensing but doctors are advised that patients intending to carry Schedule 2 and 3 drugs abroad may require an export licence. This is dependent upon the amount of drug to be exported and further details may be obtained from the Home Office by telephoning 0171-273 3806. Applications for licences should be sent to the Home Office, Drugs Branch, Queen Anne's Gate, London SW4H 9AT.

Controlled drugs and drug dependence

There is no standard application form but applications must be supported by a letter from a doctor giving details of:

- the patient's name and current address;
- · the quantities of drugs to be carried:
- the strength and form in which the drugs will be dispensed;
- the dates of travel to and from the United Kingdom

Ten days should be allowed for processing the application.

Individual doctors who wish to take Controlled Drugs abroad while accompanying patients, may similarly be issued with licences. Licences are not normally issued to doctors who wish to take Controlled Drugs abroad solely in case a family emergency should arise.

These import/export licences for named individuals do not have any legal status outside the UK and are only issued to compty with the Misuse of Drugs Act and facilitate passage through UK Customs control. For clearance in the country to be visited it would be necessary to approach that country's consulate in the UK.

Misuse of Drugs Act

The Misuse of Drugs Act, 1971 prohibits certain activities in relation to 'Controlled Drugs', in particular their manufacture, supply, and possession. The penalties applicable to offences involving the different drugs are graded broadly according to the harmfulness attributable to a drug when it is misused and for this purpose the drugs are defined in the following three classes:

- Class A includes; affentanil, cocame, dextromoramide, diamorphine (heroin), dipipanone, lysergide (LSD), methadone, morphine, opium, pethidine, pheneyelidine, and class B substances when prepared for injection
- Class B includes oral amphetamines barbiturates, cannabis, cannabis resin, codeine, ethylmorphine, glutethimide, pentazocine, phenmetrazine, and pholcodine
- Class C includes: certain drugs related to the amfetamines such as benzphetamine and chlorphentermine, buprenorphine, diethylpropion, mazindol, meprobamate, pemoline, pipradrol, most benzodiazepines, androgenic and anabolic steroids, clenbuterol, chottome gonadotrophin (BCG), non human chorronic gonadotrophin, somatotropin, somatrem, and somatropin

The Misuse of Drugs Regulations 1985 define the classes of person who are authorised to supply and possess controlled drugs while acting in their professional capacities and lay down the conditions under which these activities may be carried out. In the regulations drugs are divided into five schedules each specifying the requirements governing such activities as import, export, production, supply, possession, prescribing, and record keeping which apply to them.

Schedule I includes drugs such as cannabis and lysergide which are not used medicinally Possession and supply are prohibited except in accordance with Home Office authority

scriptions, safe custody (except for secobarbital), the need to keep registers, etc. (unless exempted in Schedule 3 includes the barbiturates (except secobarbi-

tal, now schedule 2), buprenorphine, diethylpropion, flunitrazepam, mazindol, meprobamate, pentazocine, phentermine, and temazepam. They are subject to the special prescription requirements (except for phenobarbital and temazepam, see p. 6) but not to the safe custody requirements (except for buprenorphine, diethylpropion, flunitrazepam, and temazepam) nor to the need to keep registers (although there are requirements for the retention of invoices for 2

Schedule 4 includes in Part II 33 benzodiazenines (flunitrazepam and temazepam are now in schedule and pemoline which are subject to minimal control. Part I includes androgenic and anabolic steroids. cleabuterol, chorionic gonadotrophin (HCG), nonhuman chorionic gonadotrophin. somatotronin somatrem, and somatropin. Controlled drug prescription requirements do not apply and Schedule 4 Con-Drugs are not subject to safe custody requirements

Schedule 5 includes those preparations which, because of their strength, are exempt from virtually all Controlled Drug requirements other than retention of invoices for two years.

Notification of drug misusers

In May 1997, the Misuse of Drugs (Supply to Addicts) Regulations 1997 revoked the requirement for doctors to send to the Home Office particulars of drug addicts. However, doctors are expected to report on a standard form cases of drug misuse to their local Drug Misuse Database (DMD)-see below for contact telephone numbers

A report (notification) to the Drug Misuse Database should be made when a patient first presents with a drug problem or re-presents after a gap of six months or more. All types of problem drug misuse should be reported including opioid, benzodiazepine, and CNS stimulant.

The Drug Misuse Databases are now the only national and local source of epidemiological data on people presenting with problem drug misuse and as such provide valuable information to those working with, and those planning services for drug misusers. The databases cannot however be used as a check on multiple prescribing for drug addicts because the data are anonymised.

Enquiries about the regional and national Drug Misuse Databases (including requests for supplies of notification forms) can be made by contacting one of the centres listed below:

In Northern Ireland, the Misuse of Drugs (Notification of and Supply to Addicts) (Northern Ireland) Regulations 1973 require doctors to send particulars of persons whom they consider to be addicted to certain controlled drugs to Chief Medical Officer of the Department of Health and Social Services. The Northern Ireland contacts are:

Medical contact: Dr G. R. Mock C3 Castle Buildings Belfast BT4 3PP Telephone 01232 520710

Administrative contact: Health Promotion Branch C4.22 Castle Buildings Relfast BT4 3PP Telephone 01232 520532

Prescribing of diamorphine (heroin), dipipanone, and cocaine for addicts

The Misuse of Drugs (Supply to Addicts) Regulations 1997 require that only medical practitioners who hold a special licence issued by the Home Secretary may prescribe, administer or supply diamorphine, dipipanone¹ (Diconal⁹) or cocaine in the treatment of drug addiction; other practitioners must refer any addict who requires these drugs to a treatment centre. Whenever possible the addict will be introduced by a member of staff from the treatment centre to a pharmacist whose agreement has been obtained and whose pharmacy is conveniently sited for the patient. Prescriptions for weekly supplies will be sent to the pharmacy by post and will be dispensed on a daily basis as indicated by the doctor. If any alterations of the arrangements are requested by the addict, the portion of the prescription affected must be represcribed and not merely altered. General practitioners and other doctors may still prescribe diamorphine, dipipanone, and cocaine for patients (including addicts) for relief of pain due to organic disease or injury without a spe

For prescription-writing guidelines, see p. 6.

^{1.} Dipipanone in Diconal® tablets has been much misused by opioid addicts in recent years. Doctors and others should be suspicious of people who ask for the tablets, especially if temporary residents.

Solver a residency to being

Adverse reactions to drugs

Any drug may produce unwanted or unexpected adverse reactions. Detection and recording of these is of vital importance. Doctors and pharmacists are urged to help by reporting adverse reactions to:

Medicines Control Agency CSM Freepost London SWS 5BR (0800 731 6789)

Prepaid Yellow Cards for reporting are available from the above address and are also bound in this book (inside back cover).

A 24-hour Freetone service is available to all parts of the UK for advice and information on suspected adverse drug reactions, contact the National Yellow Card Information Service at the MCA on 0800 731-6789. Outside office hours a telephone-answering machine will take messages.

The following regional centres also collect data:

CSM Mersey Freepost Liverpool L3 3AB (0151-794-8113) CSM Wales Freepost Cardiff CF4 1ZZ (01222 744181 Direct Line)

CSM Northern Freepost 1085 Newcastle upon Tyne NEI IBR (0191/2/32/1525/Ducci/Line) CSM West Midkaids Freepost SW 2994 Bunungham B18-7BR [No telephone number]

The CSM's Adverse Drug Reactions On-line Information Tracking (ADROIT) facilitates the monitoring of adverse drug reactions.

Suspected adverse reactions to any therapeutic agent should be reported, including drugs (self-medication as well as prescribed ones), blood products, vaccines, X-ray contrast media, dental or surgical materials, intra-uterine devices, herbal products, and contact lens fluids.

NEWER DRUGS. These are indicated by the symbol Ψ . Doctors and pharmacists are asked to report all suspected reactions (i.e. any adverse or any unexpected event, however intion, which could concernably be attributed to the drug). Reports should be made despite uncertainty about a causal relationship, irrespective of whether the reaction is well recognized, and even if other drugs have been given concurrently.

ESTABLISHED DRUGS AND VACCINES. Doctors and pharmacists are asked to report all serious suspected reactions, including those that are tatal, literaterating, disabling, incapacitating, or which result in or prolong bospitalisation; they should be reported even if the effect is well recognised.

Examples include anaphylaxis, blood disorders, endocrine disturbances, effects on feethifty, haemorthage from any site, rend impairment, jain dice, ophthalmic disorders, severe CNS effects, severe skin reactions, reactions in pregnant women and any drug interactions. Reports of serious adverse reactions are required to enable comparis ion with other drugs of a similar class. For established drugs doctors and pharmacists are asked not to report well-known, relatively minor side effects such as dry mouth with tricyclic antidepressants, constipation with opioids, or nausea with digoxin.

Special problems

Delayed drug effects. Some feactions (e.g. cancers, chlorospinic retinopathy, and retroperitonical librosis) may become manifest months or years affect exposure. Any suspicion of such an association should be reported.

The elderly. Particular vigilance is required to identify adverse reactions in the elderly

Congential abnormalities. When an infant is born with a congenital abnormality or there is a mall formed abouted fetus doctors are asked to consider whether this might be an adverse reaction to a drug and to report all drugs uncluding self-medications taken during pregnancy.

Children. Particular vigilance is required to identify adverse reactions in children, including those due to the unfrensed use of medicines, all suspected reactions should be reported.

Prevention of adverse reactions

Adverse reactions may be prevented as follows:

 Never use any drug unless there is a good indication. It the patient is pregnant do not use a drug unless the need for it is imperative.

2. Aftergy and idiosynciasy are important causes of anyerse drug reactions. Ask if the patient had previous reactions.

3. Ask if the parasit is already taking other drugs in hading self medication drugs, interactions may occur

3. Age and hepatic or retail disease may after the metabolism or exerction of drugs, so that much smaller doses may be needed. Genetic factors may also be responsible to variations in metabolism, notably of isomazid and the investigantial metabolism.

5. Prescribe as few drugs as possible and give very clear instructions to the elderly or any patient likely to misun derstand complicated instructions

6 When possible use a familiar drug. With a new drug be particularly alert for adverse reactions or unexpected events.

7. If wroms adverse reactions are hable to occur warn the patient

Defective Medicines

During the manufacture or distribution of a medicine an error or accident may occur whereby the finished product does not conform to its specification. While such a defect may impair the therapeutic effect of the product and could adversely affect the health of a patient, it should **not** be confused with an Adverse Drug Reaction where the product conforms to its specification.

The Defective Medicines Report Centre assists with the investigation of problems arising from licensed medicinal products thought to be defective and coordinates any necessary protective action. Reports on suspect defective medicinal products should include the brand or the non-proprietary name, the name of the manufacturer or supplier, the strength and disage form of the product, the product licence number, the batch number or numbers of the product, the nature of the defect, and an account of any action already taken in consequence. The Centre can be contacted at:

Presental physillanic care

Prescribing in palliative care

Palliative care is the active total care of patients whose disease is not responsive to curative freatment Control of pain, of other symptoms, and of psychological, social and spiritual problems, is par amount to provide the best quality of life for patients and their families. Careful assessment of symptoms and needs of the patient should be undertaken by a multidisciplinary team.

Specialist pulliative care is available in most areas as day hospice care, home care teams (often known as Macmillan teams), in-patient hospice care, and hospital teams. Many acute hospitals and teaching centres now have consultative, hospital based teams.

Hospice care of terminally ill patients has shown the importance of symptom control and psychosocial support of the patient and family. Families should be included in the care of the patient if they wish.

Many patients wish to remain at home with their families. Although some families may at first he alraid of caring for the patient at home, support can be provided by community nursing services, social services, voluntary agencies and hospices together with the general practitioner. The family may be reassured by the knowledge that the patient will be admitted to a hospital or hospice if the family cannot cope.

DRUG TREATMEN1. The number of drugs should be as few as possible, for even the taking of medicine may be an effort. Oral medication is usually satisfactory unless there is severe nausea and vonuting, dysphagia, weakness, or coma, in which case parenteral medication may be necessary.

Pain

Analgesies are more effective in preventing pain than in the relief of established pain; it is important that they are given regularly.

The non-opioid analgesics aspirin or paracetamol given regularly will often make the use of opioids unnecessary. Aspirin (or other NSAIDs if preferred) may also control the pain of home vermitaries; naproxen, flurbiprofen, and indometaem iscenion 10.1.1) are valuable and it necessary can be given rectally. Radiotherapy, hisphosphonates (section 6.2) and radioactive isotopes of strontium (Meravton) available from Amersham) may also be useful for pain due to bone metastases.

An opioid such as codeine or destropropoxyphene, alone or in combination with a non opioid analysis at adequate dosage, may be helpful in the control of moderate pain if non opioids alone are not sufficient. If these preparations are not control ring the pain, morphine is the most useful opioid analysis. Alternatives to morphine are hydromorphone (section 4.7.2), and transfermal fentanyltese below and section 4.7.2).

ORAL ROUTE. Morphine is given by mouth as an oral solution or as standard ('immediate release') formulation tablets regularly every 4 hours, the initial dose depending largely on the patient's previous reatment. A dose of 5–10 mg is enough to replace a

weaker analgesic (such as paracetamol or co proximal), but 10–20 mg or more is required to replace a strong one (comparable to morphine itself). If the first dose of morphine is no more effective than the previous analgesic it should be increased by 50%, the aim being to choose the lowest dose which prevents pain. The dose should be adjusted with careful assessment of the pain and the use of other drugs tuch as NSAIDS) should also be considered. Although morphine in a dose of 5–20 mg is usually adequate there should be no hesitation in increasing it stepwise according to response to 100 mg or occasionally up to 500 mg or higher if necessary. If pain occurs between doses the next dose due is increased; in the interum anadditional dose is given

Modified release preparations of morphine are an alternative to the oral solution or standard formulation tablets. Depending on the formulation of the modified-release preparation, the total darly morphine requirement may be given in two equal doses or as a single dose.

Preparations suitable for twice daily administration include MSI Continus' tablets or suspension. Oramorph SR tablets, and Zomorph supsules Preparations that allow administration of the total daily morphine requirement as a single dose include MVL* capsules. Moreap SR capsules may be given either twice daily or as a single daily dose

The starting dose of modified release preparations designed for twice daily administration is usually 10–20 mg/exery 12 hours if no other analysise for only paracetawid) has been taken previously but to replace a weaker opioid analysis esuch as co-proximol) the starting dose is usually 20–30 mg/exery 12 hours. Increments should be made to the dose, not to the frequency of administration, which should remain at every 12 hours.

The effective dose of modified release preparations can alternatively be determined by giving the oral solution of morphine every 4 hours in increasing doses until the pain has been controlled, and then transferring the patient to the same total 24-tout dose of morphine given as the modified release preparation (divided into two portions to 12-hourly administration). The first dose of the modified release preparation is given 4 hours after the last dose of the oral solution.

Morphine, as oral solution or standard formulation tablets, should be prescribed tor breakthrough

PARTIVIERAL ROUTE. If the patient becomes unable to swallow, the equivalent intransiscular dose of morphine is half the oral solution dose; in the case of the modified release tablets it is half the total 24 hour dose (which is then divided into 6 portions to be given every 4 hours.) Diamorphine is preferred tor injection because, being more soluble, it can be given in a smaller volume. The equivalent intra-muscular (or subcutaneous) dose of diamorphine is approximately a third of the oral dose of morphing. Subcutameous infusion of diamorphine via syringe driver can be useful (for details, see p. 13).

^{1.} Studies have indicated that administration of the fast dose of the *oral science* with the first dose of the bash thed release tablets is not necessary.

RECTAL ROUTE. Morphine is also available for rectal administration as suppositories; alternatively oxycodone suppositories can be obtained on special order.

TRANSDERMAL ROUTE. Transdermal preparations of fentanyl are available (section 4.7.2). Careful conversion from oral morphine to transdermal fentanyl is necessary; a 25 micrograms/hr patch is equivalent to a total dose of morphine up to 135 mg/24 hours

GASTRO-INTESTINAL PAIN. The pain of bowel colic may be reduced by loperamide 2-4 mg 4 times daily. Hyoscine hydrobromide may also be helpful, given sublingually at a dose of 300 micrograms 3 times daily as Kwells® (Roche Consumer Health) tablets. For the dose by subcutaneous infusion using a syringe driver, see p. 13.

Gastric distension pain due to pressure on the stomach may be helped by a preparation incorporating an antacid with an antiflatulent (section 1.1.1) and by domperidone 10 mg 3 times daily before meals

MUSCLE SPASM. The pain of muscle spasm can be helped by a muscle relaxant such as diazepam 5-10 mg daily or baclofen 5-10 mg 3 times daily.

NEUROPATHIC PAIN. Tricyclic antidepressants can be useful; amitriptyline may be given initially at a dose of 10–25 mg each night and the dose increased gradually. If pain persists, an anticonvulsant such as *either* sodium valproate initially 200 mg twice daily increased to 1.6 g daily in divided doses or carbamazepine initially 200 mg at night increased to 400 mg twice daily, may be added or substituted.

Pain due to nerve compression may be reduced by a corticosteroid such as dexamethasone 8 mg daily, which reduces oedema around the tumour, thus reducing compression.

Nerve blocks may be considered when pain is localised to a specific area. Transcutaneous electrical nerve stimulation (TENS) may also help.

Miscellaneous conditions

Non-licensed indications or routes

Several recommendations in this section involve non-licensed indications or routes.

RAISED INTRACRANIAL PRESSURE. Headache due to raised intracranial pressure often responds to a high dose of a corticosteroid, such as dexamethasone 16 mg daily for 4 to 5 days, subsequently reduced to 4-6 mg daily if possible; dexamethasone should be given before 6 p.m. to reduce the risk of insomnia.

INTRACTABLE COUGH. Intractable cough may be relieved by moist inhalations or by regular administration of oral morphine hydrochloride (or sulphate) in an initial dose of 5 mg every 4 hours. Methadone linctus should be avoided because it has a long duration of action and tends to accumulate.

DYSPNOEA. Dyspnoea may be relieved by regular oral morphine hydrochloride (or sulphate) in carefully titrated doses, starting at 5 mg every 4 hours. Diazepam 5–10 mg daily may be helpful; a corticosteroid, such as dexamethasone 4–8 mg daily, may also be helpful if there is bronchospasm or partial obstruction.

EXCESSIVE RESPIRATORY SECRETION. Excessive respiratory secretion (death rattle) may be reduced by subcutaneous injection of hyoscine hydrobromide 400–600 micrograms every 4 to 8 hours; care must however be taken to avoid the discomfort of dry mouth. For the dose by subcutaneous infusion using a syringe driver, see next page.

RESTLESSNESS AND CONFUSION. Restlessness and confusion may require treatment with haloperidol 1-3 mg by mouth every 8 hours. Chlorpromazine 25-50 mg by mouth every 8 hours is an alternative, but causes more sedation. Methotrimeprazine is also used occasionally for restlessness. For the dose by subcutaneous infusion using a syringe driver, see next page

HICCUP. Hiccup due to gastric distension may be helped by a preparation incorporating an antacid with an antiflatulent (section 1.1). If this fails, metoclopramide 10 mg every 6 to 8 hours by mouth or by intramuscular injection can be added; if this also fails, chlorpromazine 10-25 mg every 6 to 8 hours can be tried.

ANOREXIA. Anorexia may be helped by prednisolone 15-30 mg daily or dexamethasone 2-4 mg daily.

CONSTIPATION. Constipation is a very common cause of distress and is almost invariable after administration of an opioid. It should be prevented if possible by the regular administration of laxatives; a faecal softener with a peristaltic stimulant (e.g. co-danthramer), or lactulose solution with a senna preparation should be used (section 1.6.2 and section 1.6.3).

FUNGATING GROWTH. Fungating growth may be treated by cleansing with a mixture of 1 part of 4% povidone-iodine skin cleanser solution and 4 parts of liquid paraffin. Oral administration of metronidazole (section 5.1.11) may eradicate the anaerobic bacteria responsible for the odour of fungating tumours; topical application (section 13.10.1.2) is also used.

CAPILLARY BLEEDING. Capillary bleeding may be reduced by applying gauze soaked in adrenaling solution 1 mg/mL (1 in 1000).

DRY MOUTH. Dry mouth may be relieved by good mouth care and measures such as the sucking of icc or pineapple chunks or the use of artificial salivic (section 12.3.5); dry mouth associated with candidiasis can be treated by oral preparations of nystation miconazole (section 12.3.2); alternatively, fluconazole can be given by mouth (section 5.2). Dry mouth may be caused by certain medication including opioids, antimuscarinic drugs (e.g. hyoscine) antidepressants and some anti-emetics; if possible an alternative preparation should be considered.

Prescribing in palliative care

:

PRURITUS. Pruritus, even when associated with obstructive jaundice, often responds to simple measures such as application of emollients (section 13.2.1). In the case of obstructive jaundice, further measures include administration of colestyramine or an anabolic steroid, such as stanozolol 5-10 mg daily; antihistamines can be helpful (section 3.4.1).

CONVULSIONS. Patients with cerebral tumours or uraemia may be susceptible to convulsions. Prophylactic treatment with phenytoin or carbamazepine (section 4.8.1) should be considered. When oral medication is no longer possible, diazepam as suppositories 10–20 mg every 4 to 8 hours, or phenobarbital by injection 50–200 mg twice daily is continued as prophylaxis. For the use of midazolam by subcutaneous infusion using a syringe driver, see below.

DYSPHAGIA. A corticosteroid such as dexamethasone 8 mg daily may help, temporarily, if there is an obstruction due to turnour. See also under Dry Mouth.

NAUSEA AND VOMITING Nausea and vomiting are common in patients with advanced cancer. Ideally, the cause should be determined before treatment with anti-emetics (section 4.6) is started.

Metoclopramide has a prokinetic action and is used in a dose of 10 mg 3 times daily by mouth for nausea and vomiting associated with gastritis, gastric stasis, and functional bowel obstruction. Alternatively, cisapride 20 mg twice daily by mouth may produce a stronger prokinetic action. Drugs with antimuscarinic effects antagonise prokinetic drugs and, where possible, should not therefore be used concurrently.

Haloperidol is used in a dose of 1.5 mg daily (or twice daily if nausea continues) by mouth for most chemical causes of vomiting (e.g. hypercalcaemia, renal failure).

Nausea and vomiting may occur with opioid therapy particularly in the initial stages but can be prevented by giving an anti-emetic such as haloperidol or metoclopramide. An anti-emètic is usually necessary only for the first 4 or 5 days and therefore combined preparations containing an opioid with an anti-emetic are not recommended because they lead to unnecessary anti-emetic therapy (and associated side-effects when used long-term).

Cyclizine is given in a dose of 50 mg up to 3 times daily by mouth. It is used for nausca and vomiting due to mechanical bowel obstruction, raised intracranial pressure, and motion sickness.

Anti-emetic therapy should be reviewed every 24 hours; it may be necessary to substitute the anti-emetic or to add another one.

Methotrimeprazine (levomepromazine) 12.5-25 mg daily by mouth may be used if first-line antiemetics are inadequate. Dexamethasone 8-16 mg daily by mouth may be used as an adjunct.

For the administration of anti-emetics by subcutaneous infusion using a syringe driver, see below.

For the treatment of naisea and vomiting associated with cancer chemotherapy, see section 8.1.

INSOMNIA. Patients with advanced cancer may not sleep because of discomfort, cramps, night sweats, joint stiffness, or fear. There should be appropriate treatment of these problems before hypnotics are used. Benzodiazepines (e.g. temazepam) may be useful (section 4.1.1).

HYPERCALCAEMIA, See section 9.5.1.2

Syringe drivers

Although drugs can usually be administered by mouth to control the symptoms of advanced cancer, the parenteral route may sometimes be necessary. If the parenteral route is necessary, repeated administration of intramuscular injections can be difficult in a cachectic patient. This has led to the use of a portable syringe driver to give a continuous subcutaneous infusion, which can provide good control of symptoms with little discomfort or inconvenience to the patient.

Syringe driver rate settings. Staff using syringe drivers should be adequately trained and different rate settings should be clearly identified and differentiated; incorrect use of syringe drivers is a common cause of drug errors.

Indications for the parenteral route are:

- the patient is unable to take medicines by mouth owing to nausea and vomiting, dysphagia, severe weakness, or coma;
- there is malignant bowel obstruction in patients for whom further surgery is mappropriate (avoiding the need for an intravenous infusion or for insertion of a nationatric tobe;
- occasionally when the patient does not wish to take regular medication by mouth

NAUSEA AND VOMITING. Haloperidol is given in a subcutaneous infusion dose of 2.5-10 mg/24 hours.

Methotrimeprazine causes sedation in about 50% of patients; it is given in a subcutaneous infusion dose of 25–200 mg/24 hours, although lower doses of 5-25 mg/24 hours may be effective with less sedation.

Cyclizine is particularly liable to precipitate if mixed with diamorphine or other drugs (see under Mixing and Compatibility, below); it is given in a *subcutaneous infusion dose* of 150 mg/24 hours.

Metoclopramide may cause skin reactions; it is given in a *subcutaneous infusion dose* of 30-100 mg/24 hours.

Octreotide (section 8.3.4.3), which stimulates water and electrolyte absorption and inhibits water secretion in the small bowel, can be used by subcuraneous infusion, in a dose of 300–600 micrograms/24 hours to reduce intestinal secretions and vomiting.

BOWEL COLIC AND EXCESSIVE RESPIRATORY SECRETIONS. Hyoscine hydrobromide effectively reduces respiratory secretions and is sedative (but occasionally causes paradoxical agitation); it is given in a subcutaneous infusion dose of 0.6 2.4 mg/24 hours.

Hyoscine butylbromide is effective in bowel colic, is less sedative than hyoscine hydrobromide, but is not always adequate for the control of respiratory secretions; it is given in a subcutaneous infusion dose of 20-60 mg/24 hours (important: this dose of hyoscine butylbromide must not be confused with the much lower dose of hyoscine hydrobromide, above).

Glycopyrronium 0.6 1.2 mg/24 hours may also be used.

RESTLESSNESS AND CONFUSION Haloperidol has little sedative effect; it is given in a subcutancous infusion dose of 5-15 mg/24 hours.

Methotrimeprazine has a sedative effect; it is given in a subcutaneous infusion dose of 50 → 200 mg/24 hours

14 Prescribing in palliative care

Midazolam is a sedative and an antiepileptic, and is therefore suitable for a very restless patient; it is given in a *subcutaneous infusion dose* of 20–100 mg/24 hours.

CONVULSIONS. If a patient has previously been receiving an antiepileptic or has a primary or secondary cerebral tumour or is at risk of convulsion (e.g. owing to uraemia) antiepileptic medication should not be stopped. Midazolam is the benzodiazepine antiepileptic of choice for continuous subcutameous infusion, and is given in a dose of 20–40 mg/24 hours.

PAIN CONTROL. Diamorphine is the preferred opioid since its high solubility permits a large dose to be given in a small volume (see under Mixing and Compatibility, below). The table on the next page gives the approximate doses of morphine by mouth (as oral solution or standard formulation tablets or as modified-release tablets) equivalent to diamorphine by injection (intramuscularly or by subcutaneous infusion).

MIXING AND COMPATIBILITY. The general principle that injections should be given into separate sites (and should not be mixed) does not apply to the use of syringe drivers in palliative care. Provided that there is evidence of compatibility, selected injections can be mixed in syringe drivers. Not all types of medication can be used in a subcutaneous infusion. In particular, chlorpromazine, prochlorperazine and diazepam are contra-indicated as they cause skin reactions at the injection site; to a lesser extent cyclizine and methotrimeprazine may also sometimes cause local irritation.

In theory injections dissolved in water for injections are more likely to be associated with pain (possibly owing to their hypotonicity). The use of physiological saline (sodium chloride 0.9%) however increases the likelihood of precipitation when more than one drug is used: moreover subcutaneous infusion rates are so slow (0.1–0.3 ml /hour) that pain is not usually a problem when water is used as a diluent.

Diamorphine can be given by subcutaneous int sion in a strength of up to 250 mg/mL; up to strength of 40 mg/mL either water for injections physiological saline (sodium chloride 0.9%) is suitable diluent—above that strength only water tinjections is used (to avoid precipitation).

The following can be mixed with diamorphine:

Cyclizine¹
Dexamethasone²
Haloperidol³
Hyoscine butylbromide

Hyoscine hydrobromide Methotrimeprazine Metoclopramide⁴ Midazolam

Subcutaneous infusion solution should be mortored regularly both to check for precipitation (ardiscoloration) and to ensure that the infusion is runing at the correct rate.

PROBLEMS ENCOUNTERED WITH SYRING DRIVERS. The following are problems that may encountered with syringe drivers and the action the should be taken:

- if the subcutaneous infusion runs too quickly chathe rate setting and the calculation;
- if the subcutaneous infusion runs too slowly che the start button, the battery, the syringe driver, cannula, and make sure that the injection site is inflamed;
- if there is an injection site reaction make sure that site does not need to be changed—firmness or swaing at the site of injection is not in itself an indicatfor change, but pain or obvious inflammation is.
- 1. Cyclizine may precipitate at concentrations above 10 mg/mL or in the presence of physiological saline as the concentration of diamorphine relative to cyclizincreases; mixtures of diamorphine and cyclizine are also liable to precipitate after 24 hours.
- Special care is needed to avoid precipitation of dexamethasone when preparing.
- 3. Mixtures of haloperidol and diamorphine are liable precipitate after 24 hours if haloperidol concentration above 2 mg/mL.
- Under some conditions metoclopramide may becondiscoloured; such solutions should be discarded.

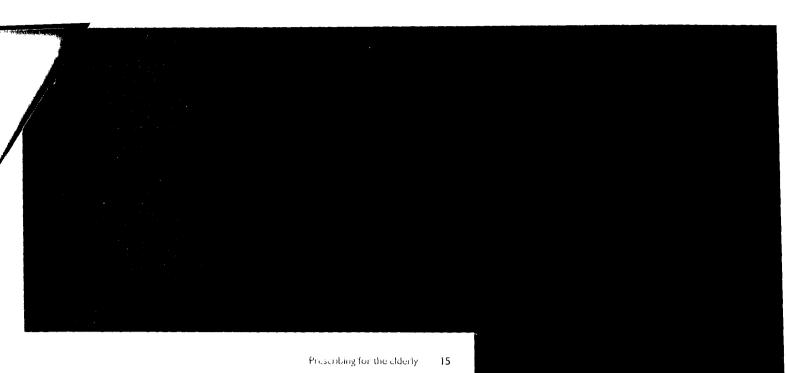

Equivalent doses of morphine sulphate by mouth (as oral solution or standard tablets or as modified-release table or of diamorphine hydrochloride by intramuscular injection or by subcutaneous infusion

These equivalences are approximate only and may need to be adjusted according to response

ORAL MORPHINE		PARENTERAL DIAMORPHINE	
Morphine sulphate oral solution or standard tablets	Morphine sulphate modified-release tablets	Diamorphine hydrochloride by intramuscular injection	Diamorphine hydrochloride by subcutaneous infusion
every 4 hours	every 12 hours	every 4 hours	every 24 hours
5 mg	20 mg	2.5 mg	15 mg
10 mg	30 mg	5 mg	20 mg
15 mg	50 mg	5 mg	30 mg
20 mg	60 mg	7.5 mg	45 mg
30) mg	90 mg	10 mg	60 mg
40 mg	120 mg	15 mg	90 mg
60 mg	180 mg	20 mg	120 mg
80 mg	240 mg	30 mg	180 mg
100 mg	300 mg	40 mg	240 mg
130 mg	400 mg	50 mg	300 mg
160 mg	500 mg	60 mg	360 mg
200 mg	600 mg	70 mg	400 mg

If breakthrough pain occurs give a subcutaneous (preferable) or intramuscular injection of diamorphine equiva to one-sixth of the total 24-hour subcutaneous infusion dose. It is kinder to give an intermittent bolus injec subcutaneously—absorption is smoother so that the risk of adverse effects at peak absorption is avoided (an e better method is to use a subcutaneous butterly needle).

To minimise the risk of infection no individual subcutaneous sinfusion solution should be used for longer than 24 hor

Prescribing for the elderly

Old people, especially the very old, require special care and consideration from prescribers.

POLYPHARMACY. Elderly patients often receive multiple drugs for their multiple diseases. This greatly increases the risk of drug interactions as well as adverse reactions. Moreover, symptoms such as headache, sleeplessness, and lightheadedness which may be associated with social stress, as in widowhood, loneliness, and family dispersal can lead to further prescribing, especially of psychotropics. The use of drugs in such cases can at best be a poor substitute for effective social measures and at worst pose a serious threat from adverse reactions. Whilst unnecessary medication should be avoided, elderly patients should not be denied effective treatments such as those for stroke prophylaxis in atrial fibrillation or for ostcoporosis.

FORM OF MEDICINE. Frail elderly patients may have difficulty swallowing tablets; if left in the mouth, ulceration may develop. They should always be encouraged to take their tablets or capsules with enough fluid, and in some cases it may be helpful to discuss with the patient the possibility of prescribing the drug as a liquid if available.

MANIFESTATIONS OF AGEING. In very old subjects, manifestations of normal ageing may be mistaken for disease and lead to inappropriate prescribing. For example, drugs such as prochlor-perazine are commonly misprescribed for giddiness due to age-related loss of postural stability. Not only is such treatment ineffective but the patient may experience serious side-effects such as parkinsonism, postural hypotension, and confusion.

SELF-MEDICATION. Self-medication with overthe-counter products or with drugs prescribed for a previous illness (or even for another person) may be an added complication. Discussion with both the patient and relatives as well as a home visit may be needed to establish exactly what is being taken.

SENSITIVITY. The ageing nervous system shows increased susceptibility to many commonly used drugs, such as opioid analgesics, benzodiazepines, antipsychotics, and antiparkinsonian drugs, all of which must be used with caution.

Pharmacokinetics

The most important effect of age is reduction in renal clearance. Many aged patients thus possess only limited reserves of renal function, exerctedrags slowly, and are highly susceptible to nephrotrosic drugs. Acute illness may lead to rapid reduction in renal clearance, especially if accompanied by dehydration. Hence, a patient stabilised on a drug with a narrow margin between the therapeutic and the toxic dose (e.g. digoxin) may rapidly develop adverse effects in the aftermath of a myocardial infarction or a respiratory-tract infection. Metabolism of drugs in the liver may be reduced in the elderly.

The net result of pharmacokinetic changes is that the tissue concentration of a drug is commonly increased by over 50%, and aged and debilitated patients may show even larger changes.

Adverse reactions

Adverse reactions often present in the elderly in a vague and non-specific fashion. Confusion is often the presenting symptom teaused by almost any of the commonly used drugs). Other common manifestations are constipation (with antimuscarines and many tranquillisers) and postural hypotension and falls (with diuretics and many psychotropies).

HYPNOTICS. Many hypnotics with long half-lives have serious hangover effects of drowsiness, unsteady gait, and even slurred speech and confusion. Those with short half-lives should be used but they too can present problems (section 4.1.1). Short courses of hypnotics are occasionally useful for helping a patient through an acute illness or some other crisis but every effort must be made to avoid dependence. Benzodiazepines impair balance, which may result in falls.

DIURETICS. Diureties are overprescribed in old age and should **not** be used on a long-term basis to treat simple gravitational ocdema which will usually respond to increased movement, raising the legs, and support stockings. A few days of diuretic treatment may speed the clearing of the ocdema but it should rarely need continued drug therapy.

NSAIDs. Bleeding associated with *aspirin* and *other NSAIDs* is more common in the elderly who are more likely to have a fatal or serious outcome. NSAIDs are also a special hazard in patients with cardiac disease or renal impairment which may again place older patients at particular risk.

Owing to the increased susceptibility of the elderly to the side-effects of NSAIDs the following recommendations are made:

- for asteoarthritis, soft-tissue lesions and back pain first try measures such as weight reduction, warmth, exercise and use of a walking stick;
- for osteoarthritis, soft tissue lesions, back pain and rheumatoid arthritis avoid giving an NSAID unless paracetanod (alone or with a low dose of an opioid analgesic as in co-codamol 8/500 or co-dydramol 10/500) has failed to relieve the pain adequately;
- where a paracetamol preparation has failed to relieve the pain adequately add a very low dose of an NSMD to the paracetamol preparation (starting with ibuprofen). For advice on prophylaxis of NSAID induced peptic ulcers (where continued treatment with NSAIDs is necessary), see section 1.3.
- if an NSAID is considered necessary monitor the patient for gastro intestinal bleeding for 4 weeks (and for a similar time on switching to another NSAID). For the management of NSAID-associated peptic ulcers, see section 1.3
- · do not give two NSAIDs at the same time

OTHER DRUGS. Other drugs which commonly cause adverse reactions are antiparkinsonian drugs, antihypertensives psychotropics and dispain. The usual maintenance dose of digoxin in very old patients is 125 micrograms daily (62.5 micrograms in those with renal disease); lower doses are often inadequate but toxicity is common in those given 250 micrograms daily.

Drug-induced blood disorders are much more

Drug-induced blood disorders are much more common in the elderly. Therefore drugs with a tendency to cause bone marrow depression (e.g. co-trimovazole, miamserin) should be avoided unless there is no acceptable alternative.

The elderly generally require a lower maintenance dose of warfarin than younger adults; once again, the outcome of bleeding tends to be more serious

Guidelines

First always question whether a drug is indicated at all.

LIMIT RANGE. It is a sensible policy to prescribe from a limited range of drugs and to be thoroughly familiar with their effects in the elderly.

REDUCE DOSE. Dosage should generally be substantially lower than for younger patients and it is common to start with about 50% of the adult dose. Some drugs (e.g. long-acting antidiabetic drugs such as glibenclamide and chlorpropamide) should be avoided altogether.

REVIEW REGULARLY. Review repeat prescriptions regularly. It may be possible to stop the drug (e.g. digoxin can often be withdrawn) or it may be necessary to reduce the dose to match diminishing renal function.

SIMPLIFY REGIMENS. Elderly patients benefit from simple treatment regimens. Only drugs with a clear indication should be prescribed and whenever possible given once or twice daily. In particular, regigmens which call for a confusing array of dosage intervals should be avoided.

EXPLAIN CLEARLY. Write full instructions on every prescription (including repeat prescriptions) so that containers can be properly labelled with full directions. Avoid imprecisions like 'as directed'. Child-resistant containers may be unsuitable.

REPEATS AND DISPOSAL. Instruct patients what to do when drugs run out, and also how to dispose of any that are no longer necessary. Try to prescribe matching quantities.

If these guidelines are followed most elderly people will cope adequately with their own medicines. If not then it is essential to enrol the help of a third party, usually a relative or a friend.
